PRESENTATION SCRIPT - 10 MINUTES

OpenID Vision

Know when to match. Know when to reject.

A step-by-step guide for presenting to HR: what to say, what to show, with one everyday example.

The one sentence to remember

"It recognises the people it knows, says unknown to everyone else - even a stranger in the same uniform - and asks a human when it is not sure."

Your 10 minutes at a glance

0:00	The problem, in a story
1:00	The everyday example (office door)
2:30	Live demo: press one button
5:30	Three answers - and the human in the loop
7:00	Responsible use: consent, privacy, limits
8:30	What was built, and what it shows about the work
9:30	Close

Independent technical prototype responding to the Zed Digital PS-1 assignment - not an official Zed Digital product. Research use with consenting people only.

Before you start (5 minutes, once)

1. Double-click **Start OpenID Vision.bat** (folder `D:\ps1`). Keep the black window open. The browser opens by itself.
2. Check the top right says **Models ready**. If not, wait 30 seconds and press F5.
3. You will land on the **home page (Command Center)**. Do not press "Run the example" yet - you will do it live, it takes about 10 seconds.
4. Have this PDF open on a second screen or printed. Read the grey **Say** boxes aloud in your own words; the blue **Do** boxes are the clicks.

Rules for the room. Use only people who agreed to be shown. The example uses public-domain photographs, so nobody in the audience is ever used without consent.

Who you are talking to - and what they care about

HR CARES ABOUT	SO YOU SHOW
Is the decision fair and explainable?	Every answer comes with its score and its reason in words.
Is a human still in charge?	The third answer, **REVIEW**, means "a person decides".
Is it legal and respectful of privacy?	Consent, deletion, local-only storage, and the honest limits.
What does this say about the person who built it?	It was measured, tested (427 + 157 automated tests) and documented - and it admits what it cannot do.

Golden rule. Only say what the screen can show. If you are asked something you do not know, say: "*I don't know - here is how I would find out.*" That answer builds trust.

0:00 - 2:30 Steps 1 and 2: the problem and the everyday example

Step 1 (0:00 - 1:00) The problem, as a story

> **Say:** "Imagine a guard at an office door who only looks at **uniforms**. Anyone in the right uniform walks in - including a stranger wearing a look-alike jacket. Many computer systems that recognise people work exactly like that guard: they compare clothes and build. This project is the same guard, trained to behave properly."

Step 2 (1:00 - 2:30) The example: Priya and the office door

	WHO	WHAT HAPPENS
1	**Priya** joins the company and **agrees** to be enrolled: the system keeps her face and body fingerprint (a list of numbers, not a photo gallery).	She is now "known".
2	Next week **Priya returns** in a different jacket.	Right answer: **MATCH** - it is her.
3	**A visitor** nobody has seen, wearing the **same jacket** Priya wore when she enrolled.	Right answer: **UNKNOWN** - not enrolled.
4	Priya walks past with her back to the camera, face not visible.	Right answer: **REVIEW** - ask a person.

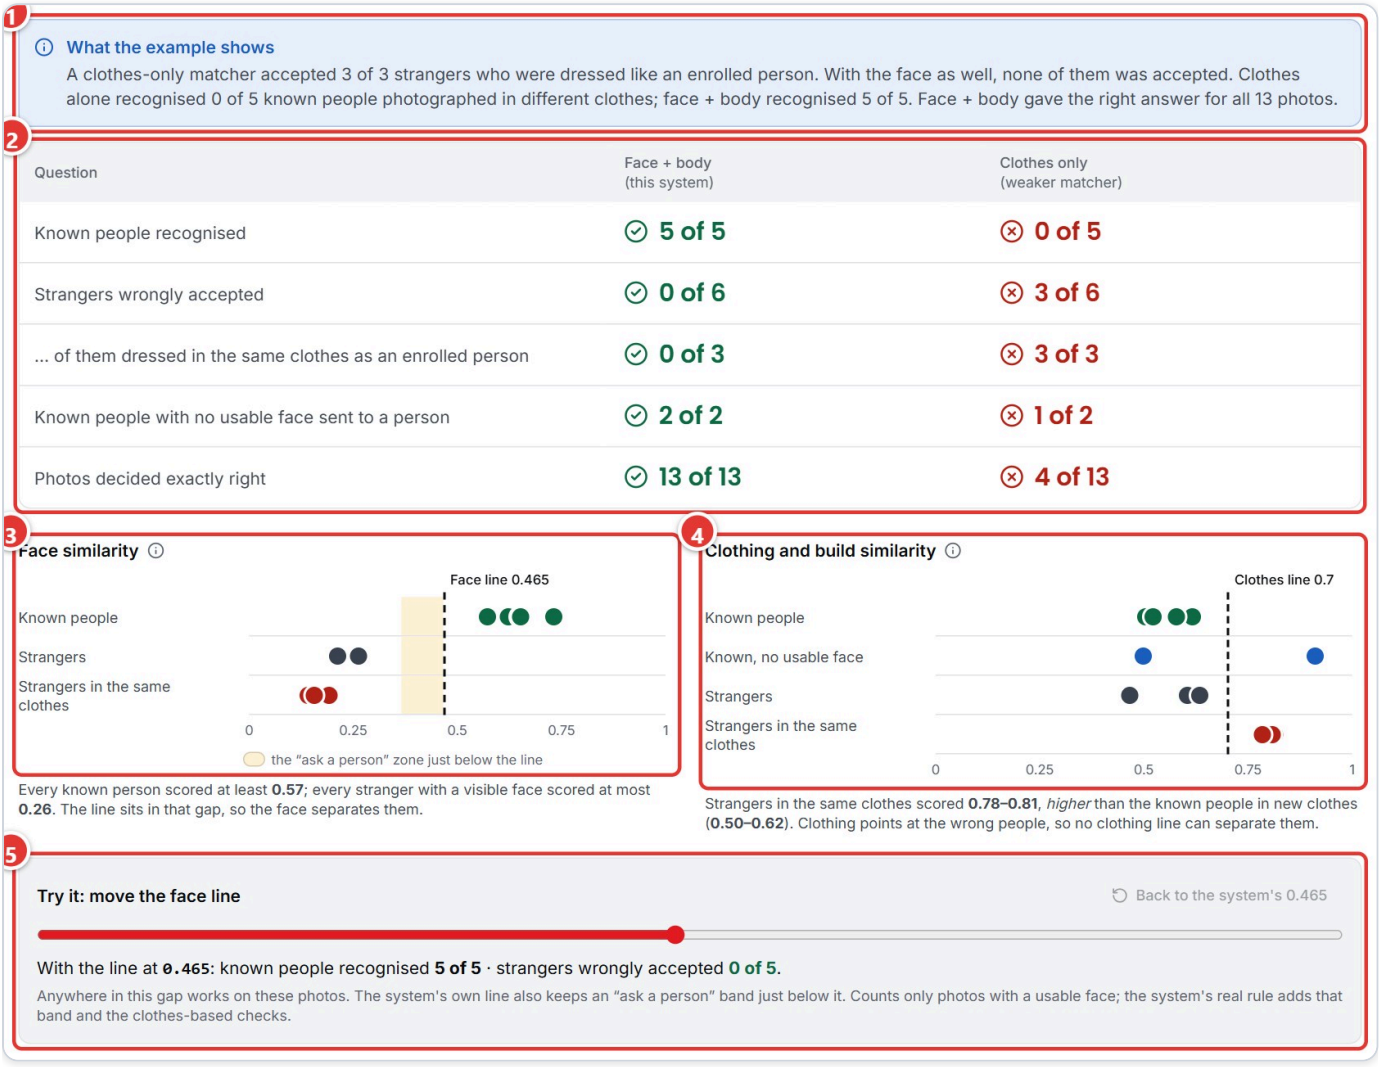

> **Say:** "A clothes-only system gets row 2 wrong - it does not recognise Priya in a new jacket - and row 3 wrong - it lets the visitor in. Our system uses the **face first** and the clothes only as support. Let me show you with real photos, not a drawing."

Why HR should care. The same question appears in access control, attendance and any automated decision about people: "*is this really who the system thinks it is - and what happens when it is not sure?*"

2:30 - 5:30 Step 3: the live demo (one button)

Do: On the home page point at the three cards: **1 Enroll people, 2 Match photos, 3 See the open-set analysis**. Then click **Run the example**. A progress bar runs for about 10 seconds.

Say: "The system now has three example people enrolled and is shown 13 photos it has never seen: known people in new clothes, strangers, and - the hard part - three strangers wearing the **same orange flight suit** as the people enrolled. Public-domain photographs, nothing is saved."

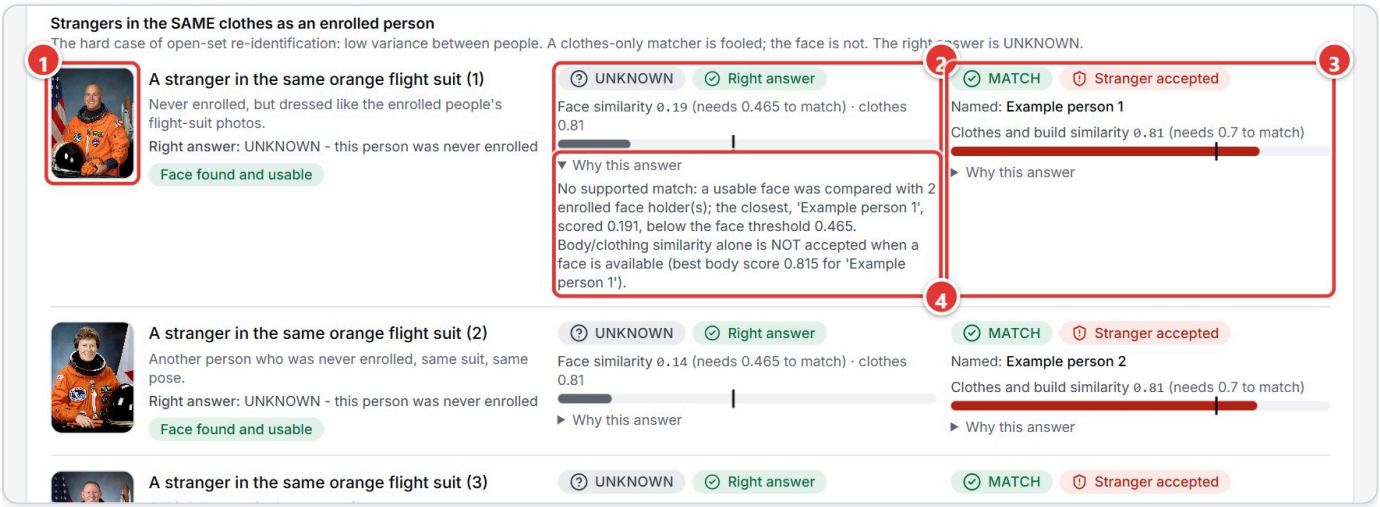

Read it in 30 seconds (point with the mouse)

QUESTION (LEFT COLUMN)	FACE + BODY (OUR SYSTEM)	CLOTHES ONLY
Known people recognised	**5 of 5**	**0 of 5**
Strangers in the **same clothes** refused	**3 of 3**	**0 of 3**
All 13 photos right	**13 of 13**	**4 of 13**

Say: "Green tick is good, red cross is not. With clothes alone, **3 of 3** strangers in the same suit were let in, and none of the five real people was recognised. With the face as well: **0 strangers let in**, and all five recognised."

2:30 - 5:30 Step 3 (continued): one photo, both answers

Do: Scroll to the group **"Strangers in the SAME clothes as an enrolled person"**. Click **Why this answer** on the first row.

- **Left:** a stranger in the same orange suit. The right answer is UNKNOWN.
- **Middle (our system):** UNKNOWN, right answer. The face looked nothing like the enrolled people (similarity **0.19**, it needed **0.465**).
- **Right (clothes only):** MATCH - **"Stranger accepted"** in red. Clothes similarity **0.81** against a line of **0.70** (a score, not a percentage).

Say: "This is the whole project in one row. The clothes said 'yes, I know this person'. The face said 'no, this is someone else'. The system trusts the face."

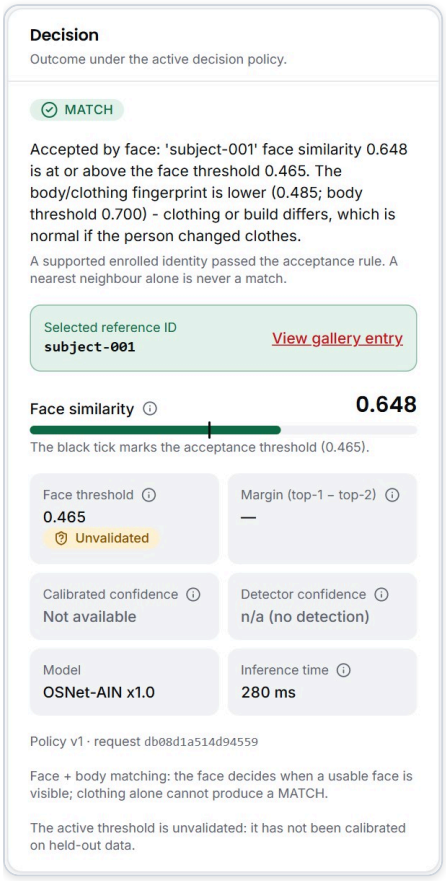

Optional (30 seconds): the slider

Do: Drag **"Try it: move the face line"** to the far left, then back with the **Back to the system's 0.465** button.

Say: "Lower the bar and strangers start getting in; raise it and real people are missed. Where to put the bar is a trade-off between convenience and safety - a decision for people, which is why the system is built to be adjustable and measured, not fixed."

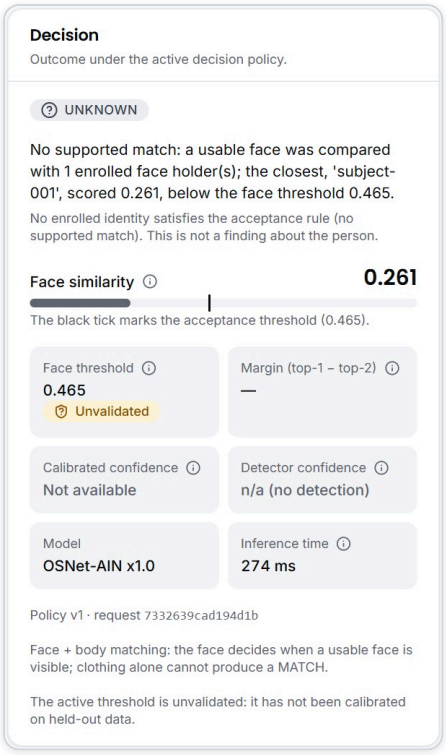

Say this before anyone asks: "This is 13 photographs - a demonstration of how it thinks, not a measurement of how accurate it is in your building."

5:30 - 7:00 Step 4: three answers, and the human in the loop

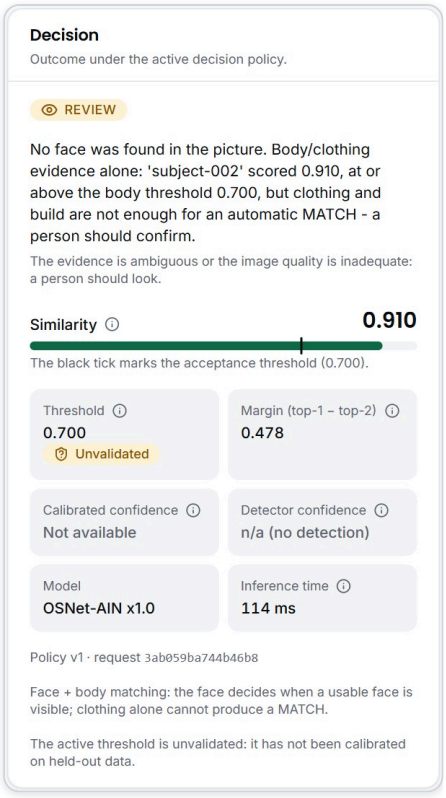

MATCH

"This is someone enrolled." Strong evidence: nothing more to do.

UNKNOWN

"Nobody enrolled matches." Not an accusation about the person.

REVIEW

"Not sure - a person decides." Poor photo or no visible face.

> **Say:** "Notice there are **three** answers, not two. The system is allowed to say 'I am not sure'. When the face is hidden, it does not guess from clothes - it hands the decision to a human. In the example, both blurred-face photos went to REVIEW."

Why this matters for HR

Explainable	Every answer shows the score, the line it had to reach, and a sentence explaining why (the **Why this answer** link).
Human oversight	Uncertain cases are routed to a person by design, not by afterthought.
Auditable	Every decision is recorded with the rule version that produced it, and can be exported.
Honest about uncertainty	The threshold is labelled **Unvalidated** on screen until it is calibrated on real data.

> **Do:** Optional: click **Match Studio** in the menu and show the empty page - "this is where you would upload a photo of a real, consenting volunteer."

7:00 - 8:30 Step 5: responsible use - say this calmly

> **Say:** "A face fingerprint is **biometric data**, so the rules around it matter as much as the technology."

TOPIC	WHAT THE SYSTEM DOES
Consent	Enrolling a person requires an explicit consent tick. Only enrolled, consenting people are ever matched.
Storage	Everything stays on this computer. No cloud, no internet, no camera feed.
Deletion	Deleting a person erases their photos and their face and body fingerprints. Uploaded query photos expire after 24 hours.
Unknown people	Never saved, grouped or tracked. UNKNOWN only means "not enrolled".
Switch-off	One setting returns to the clothes-and-body-only mode; every rule change is versioned and logged.

Limits - state them before you are asked

- **Not a phone's Face ID.** It is ordinary 2-D photo matching: no depth sensor, no check that a real person (not a photograph) is present.
- **Fairness across groups is not measured.** Accuracy by age, skin tone or gender has not been tested.
- **Tested on easy data.** The face part scored 98.9% on a standard public benchmark (LFW); the pedestrian-camera benchmark has **not** been run.
- **The example is a demonstration** of 13 photos, not an error rate for any real building.
- **Legal basis needed.** Biometric data is regulated (GDPR, India's DPDP Act, Illinois BIPA): a real deployment needs a legal basis and an impact assessment.

> **Say:** "I would rather tell you what it cannot do today than have you discover it later."

8:30 - 10:00 Steps 6 and 7: what was built, and the close

Step 6 (8:30 - 9:30) What was built - in plain words

A working web application	seven screens: add people, check a photo, check a video clip, find look-alike failures, measure accuracy, view settings, and a home page with the example.
A written decision rule	"Face first, clothes second, a human when unsure" - a small, tested piece of logic, not a black box.
Measured, not claimed	Every number on screen is computed by the system; every claim in the documents has a script that reproduces it.
Tested and documented	427 automated backend tests and 157 interface tests pass; a 30-page user manual, a jury guide and a privacy document are included.

> **Say:** "What I want you to take from this about how I work: I tested it, found a real weakness - clothes alone let strangers in - fixed it, measured the improvement, and wrote down honestly what is still unproven."

Step 7 (9:30 - 10:00) Close

> **Say:** "To summarise: it recognises people it knows, refuses strangers even in the same clothes, and asks a human when unsure. It is a prototype, built responsibly, with limits I have told you about. Thank you - I am happy to take questions."

Next steps if asked: run the pedestrian benchmark, calibrate the thresholds on real camera footage, add a check that a real person (not a photo) is present, and measure accuracy across different groups of people.

Questions HR may ask - and honest answers

Is it accurate?	The face part scored 98.9% on a standard public test; in our small end-to-end test 20 of 20 same-person photos matched and 0 of 60 strangers were accepted. In the home-page example, 13 of 13 photos were right. Accuracy on your own cameras has **not** been measured - that is the next step.
Could it discriminate against some people?	Possibly - face systems can perform differently across groups, and we have **not** measured it. That is why uncertain cases go to a person, and why it should not decide anything important on its own.
Is it legal to use on employees?	Only with a legal basis, informed consent and an impact assessment. The prototype enforces consent at enrolment; the legal decision belongs to the company and its lawyers.
Where does the data go?	Nowhere. It stays on the one computer running it. Deleting a person erases their data.
Can it be fooled by a photograph?	Yes. There is no liveness check. Real deployments add depth or infrared sensing.
Why not just use the face?	Faces are often not visible (back view, distance, blur). Then the system falls back to the body - and, because that is weaker, asks a human.
Does it track people around the building?	No. Video is checked frame by frame; nothing follows a person from frame to frame.
What would it take to use it for real?	Run the benchmark, calibrate on your cameras, add liveness checks, measure fairness, get legal approval - then a pilot with consenting volunteers.
What was your part?	Describe your own contribution truthfully (design, building, testing, documenting). Do not claim anything you did not do.
Something you do not know	"I don't know - here is how I would find out." Always acceptable.

If the demo does not work

1. Models not ready: wait 30 seconds, press F5.
2. Example button greyed out: say so, and show the screenshots in this PDF (pages 4 and 5) - they are from a real run.
3. Total failure: open `demo\JURY_DECK.pdf` (15 slides) - the same story with the measurements.
